BOPF Integration

Agenda

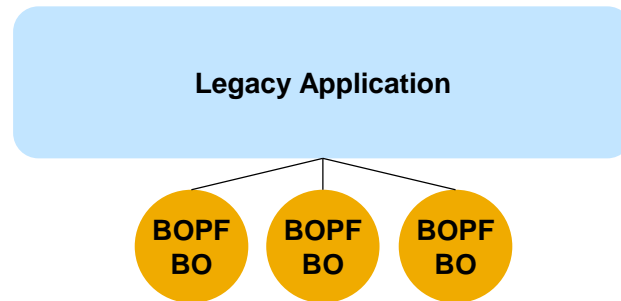

- 1. Integration of BOPF Business Objects into Legacy Applications**
(Master/Slave Transaction Manager)
- 2. Integration of Legacy Data and Functions into BOPF Business Objects**
 - a. Function Integration on Application Layer
 - b. Data Integration on Application Layer

BOPF Integration

Agenda

- 1. Integration of BOPF Business Objects into Legacy Applications (Master/Slave Transaction Manager)**
2. Integration of Legacy Data and Functions into BOPF Business Objects
 - a. Function Integration on Application Layer
 - b. Data Integration on Application Layer (Legacy DAC)

Integration of BOPF Business Objects into existing Legacy Applications

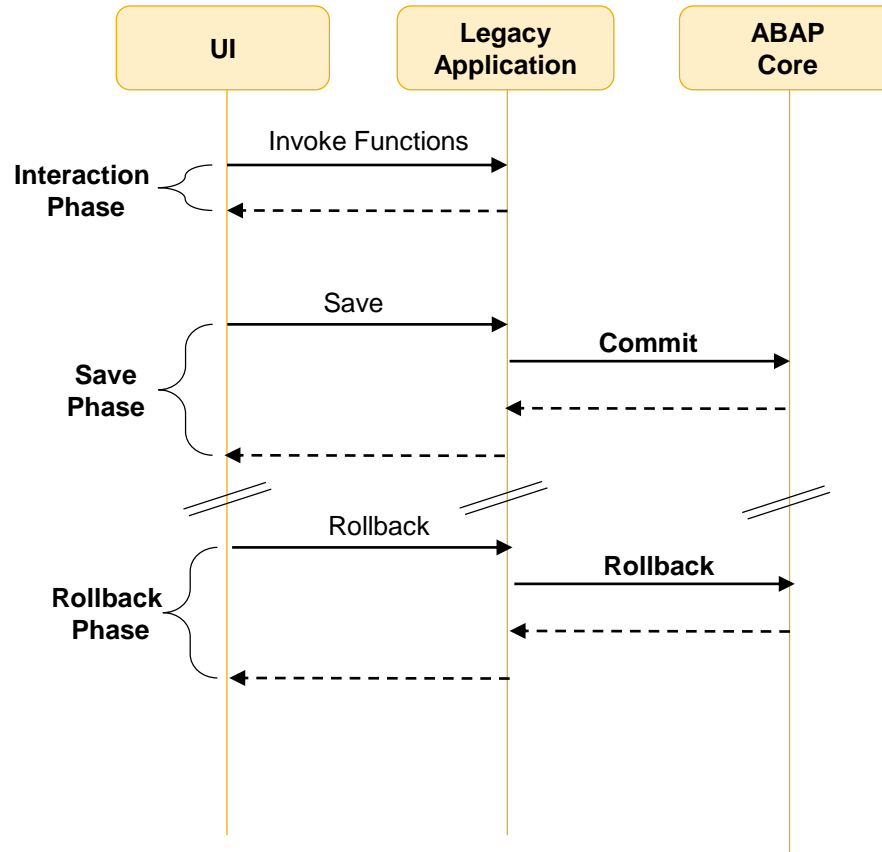

Scenario: Existing BOPF business objects need to be integrated into an application or another framework.

Issue: BOPF business objects must rely on the correct processing of the BOPF transaction phases like it is ensured using the BOPF standalone transaction manager. For instance the finalize phase must be executed to run the finalize determinations before a commit work is called.

Solution: Instead of using the (standalone) transaction manager, you have to implement an own „master“ transaction manager orchestrating both the save process of the legacy application as well as the save process of the BOPF business objects.

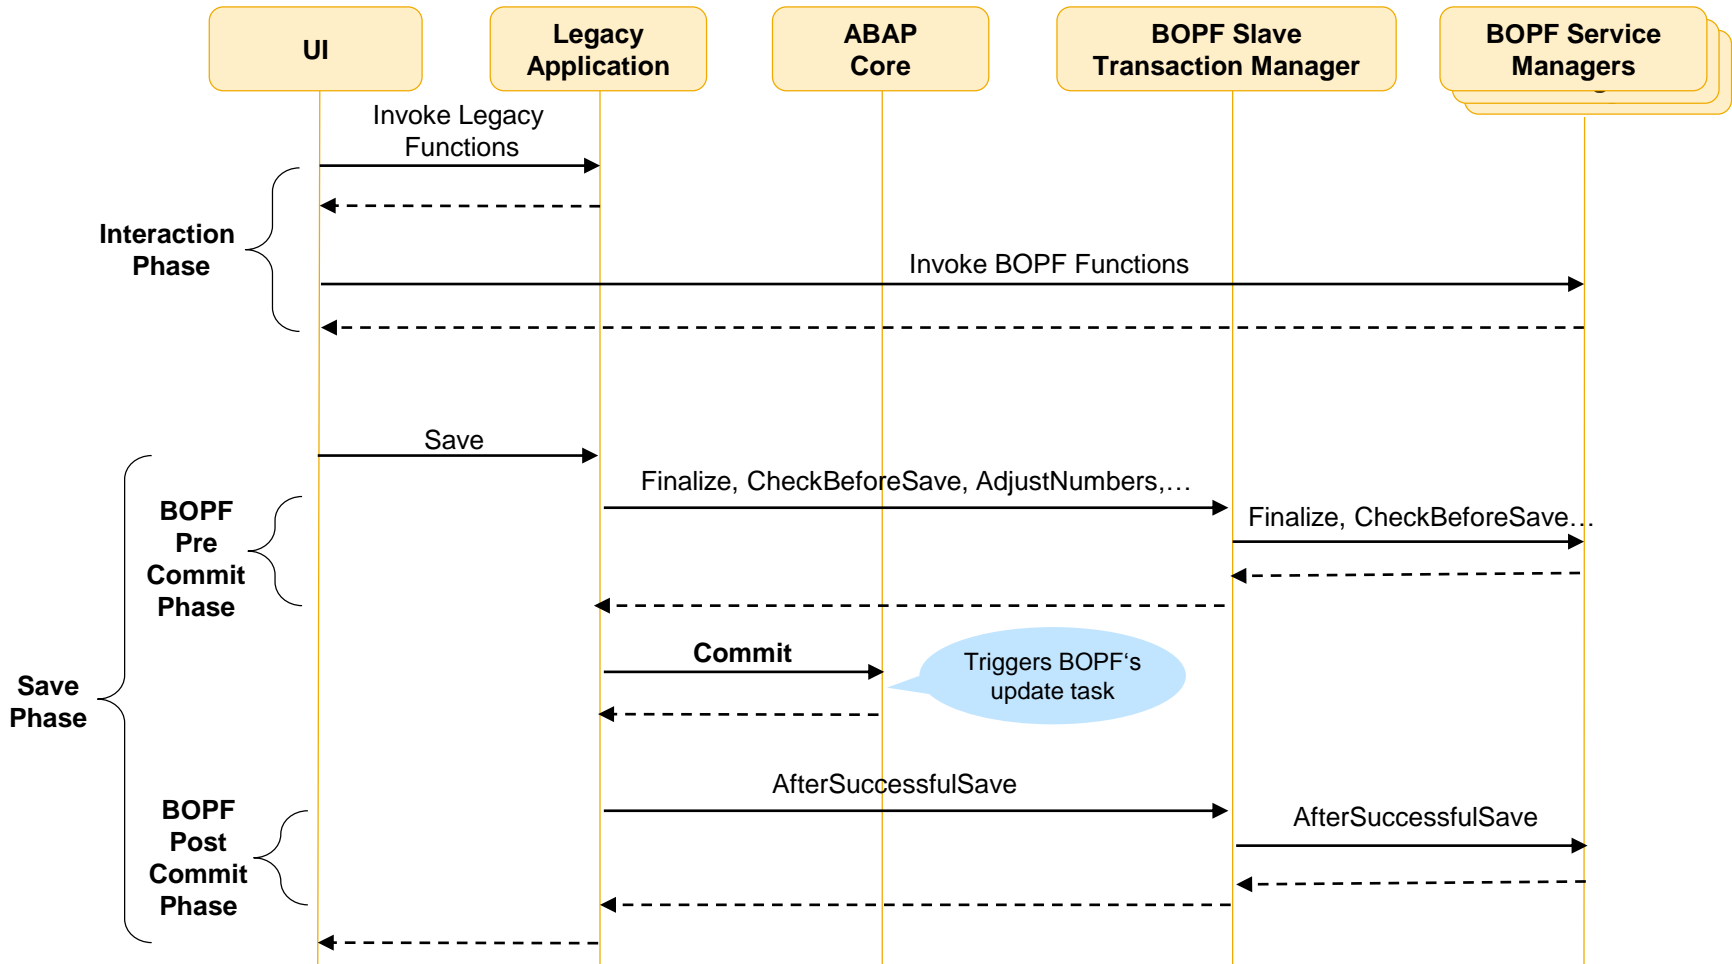

Integration of BOPF BOs into Legacy Applications (1/3)

Legacy Application

Integration of BOPF BOs into Legacy Applications (2/3)

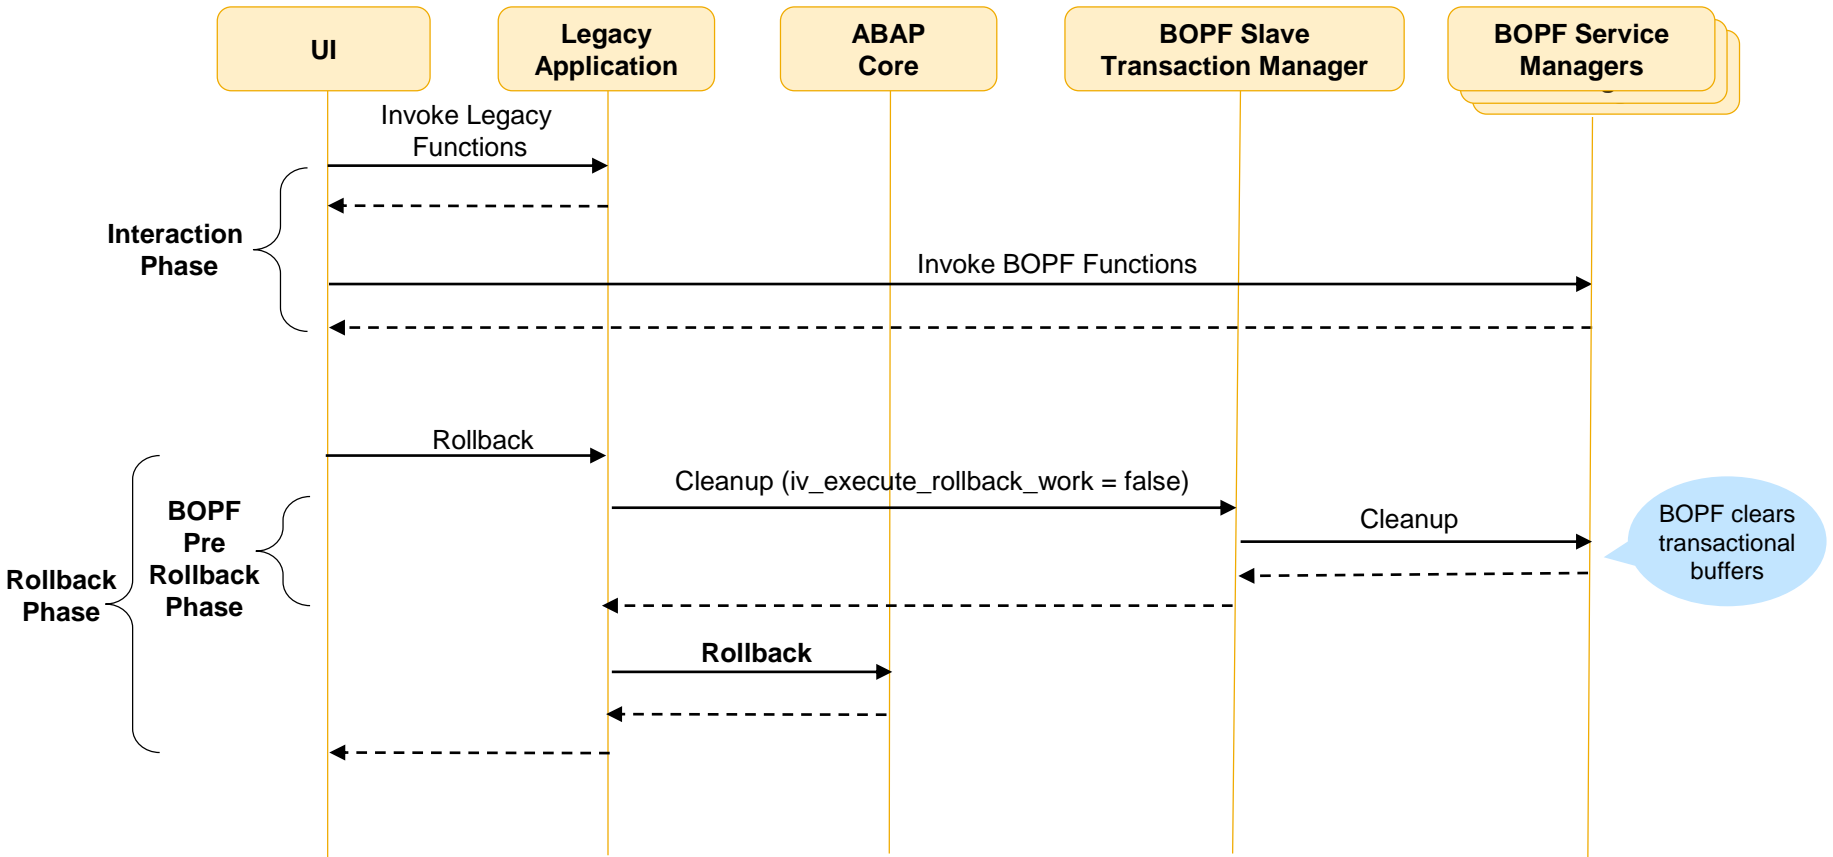

Legacy Application & BOPF – Save Phase

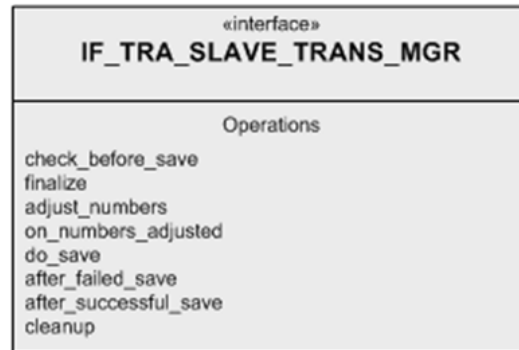

The Legacy Application is called Master Transaction Manager as it handles the COMMIT/ ROLLBACK.

Integration of BOPF BOs into Legacy Applications (3/3)

Legacy Application & BOPF – Cleanup Phase

Implementation of a Master Transaction Manager

Implement your own master transaction manager instead of using the BOPF (standalone) transaction manager. It needs to handle both the save (and cleanup) process of the BOPF BOs via the Slave Transaction Manager and the save of the legacy application. The slave manager instance can be received by the `/BOBF/CL_TRA_TRANS_MGR_FACTORY => GET_SLAVE_TRANSACTION_MANAGER()` method.

You can take the `/BOBF/CL_TRA_TRANSACTION_MGR`, method `SAVE()` as a reference of the sequence which needs to be called while save. Also implement the cleanup functionality.

BOPF Integration

Agenda

1. Integration of BOPF Business Objects into Legacy Applications
(Master/Slave Transaction Manager)
2. **Integration of Legacy Data and Functions into BOPF Business Objects**
 - a. Function Integration on Application Layer
 - b. Data Integration on Application Layer
(Legacy DAC)

Integration Object

Data

Function

Depending on the scenario, (legacy) data and (legacy) functions needs to be integrated into a BOPF based application. For instance, an existing function module must be offered to the consumer by the help of a business object.

Integration Layer

User Interface Layer

Application Layer

Database Layer

Integration can be achieved on different layers of an application. In this chapter, only the application layer is focused as it is represented by the BOPF. The possibilities of integrating on User Interface Layer and Database Layer heavily depend on the used technology.

Integration Matrix

Examples of Integration Possibilities

	Data Integration (e.g. Database Table)	Function Integration (e.g. Function Module)
User Interface Layer	e.g. Frames in HTML	e.g. UI buttons calling functions
	Content of this Presentation	
Application Layer (BOPF)	Specific BOPF Data Access Class	Encapsulation via BOPF Actions, Determinations or Validations
Database Layer	e.g. DB Views	e.g. DB trigger, stored procedures

BOPF Integration

Agenda

1. Integration of BOPF Business Objects into Legacy Applications
(Master/Slave Transaction Manager)
2. Integration of Legacy Data and Functions into BOPF Business Objects
 - a. **Function Integration on Application Layer**
 - b. Data Integration on Application Layer
(Legacy DAC)

Function Integration on Application Layer

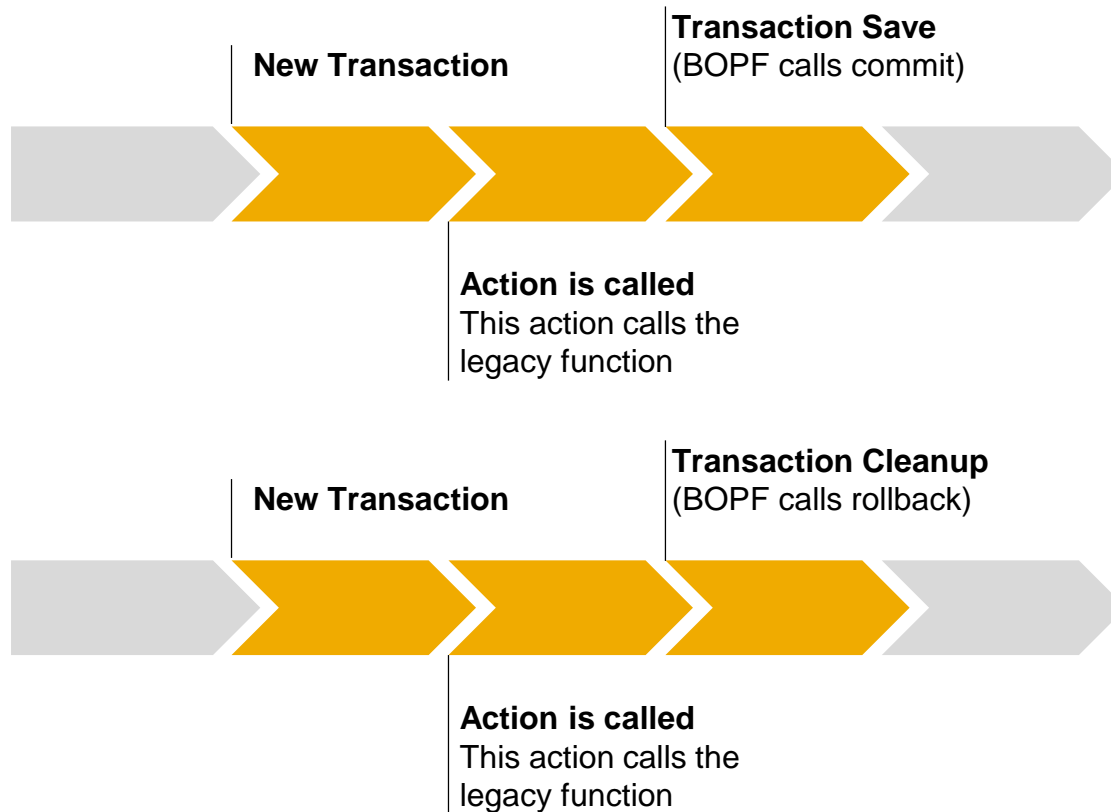

Motivation

There is an existing function module which shall be consumed via a BOPF business object. This has the advantage that BOPF UI infrastructure can be reused (e.g. user interface frameworks) and the data can be easily consumed from other BOPF business objects.

Function Integration on Application Layer

Best Practise

The legacy function is encapsulated by the help of a BOPF action (determination or validation would also be possible). Changes done by that function are saved or cleaned up by the BOPF's commit or rollback.

Issues of Integrating Functions on Application Layers

Legacy Function calls Commit or Rollback

Issue

The function to be integrated uses transactional commits and rollbacks which can't be suppressed by parameters.

Only the BOPF (or the master transaction manager if existing) is allowed to execute commits and rollbacks. If a function is calling those commands on its own, the enqueues (update locks) set by BOPF to protect changed node instances are released. This can cause inconsistencies (lost updates) in case of a foreign session.

Solution: Staging

Stage the function calls in a static variable and execute the real function call only via an „after successful save“ determination. Use a second determination configured to the „cleanup“ time to clear that static variable if the current transaction is cleaned up by the user.

Issues of Integrating Functions on Application Layers

Legacy Function has no “cleanup”/”undo” Option

Issue

The function to be integrated does not have an undo option (transaction rollback would be not sufficient).

All changes which are done during a transaction must be made undone as soon as the user cleans up the current transaction instead of saving it. Also all changes done by that functions needs to be made undone if a rollback is not sufficient.

Solution 1: Staging

Stage the function calls in a static variable and execute the real function call only via an „after successful save“ determination. Use a second determination configured to the „cleanup“ time to clear that static variable if the current transaction is cleaned up by the user.

Solution 2: Log & Compensate

Create a determination at „cleanup“ time which compensates the changes done by the integrated function. Be aware that also the compensation operations could fail.

Issues of Integrating Functions on Application Layers

Legacy Function modifies Objects which needs to be locked

Issue

The function modifies objects which needs to be locked and which might be locked by other users in parallel. If the function is called and the necessary lock is not available, the situation must not harm the transactional consistency (all or nothing paradigm)

Solution: Action Validation to get the Locks

If the function is integrated by the help of a BOPF action, you can use an action validation which acquires the necessary lock for your function up front. If the lock is not available, the action validation rejects the action execution.

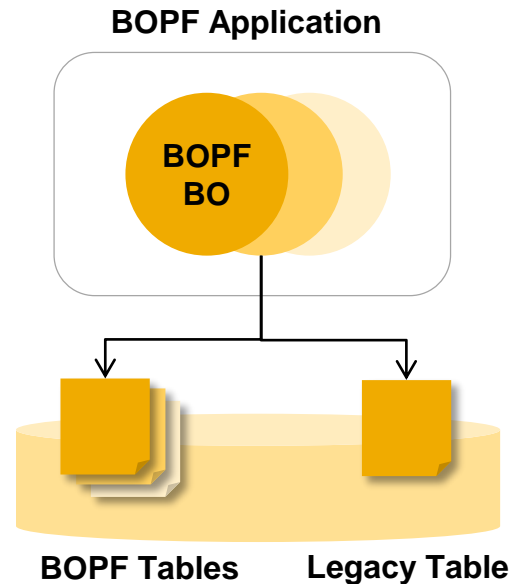

BOPF Integration

Agenda

1. Integration of BOPF Business Objects into Legacy Applications
(Master/Slave Transaction Manager)
2. Integration of Legacy Data and Functions into BOPF Business Objects
 - a. Function Integration on Application Layer
 - b. Data Integration on Application Layer
(Legacy DAC)**

Data Integration on Application Layer

Motivation

An existent legacy database table shall be integrated into a BOPF business object. It shall be represented by a node.

In contrast to directly access the table, the BOPF infrastructure (UI, extensibility) can be reused and further functionality can easily be added to the node.

Data Integration on Application Layer

Case 1: BOPF Default Persistency Layout is used

Root Database Table

Field	Type
MANDT	MANDT
DB_KEY	/BOBF/CONF_KEY (RAW16)
...	

Subnode Database Table

Field	Type
MANDT	MANDT
DB_KEY	/BOBF/CONF_KEY (RAW16)
PARENT_KEY	/BOBF/CONF_KEY (RAW16)
...	

Subsubnode Database Table

Field	Type
MANDT	MANDT
DB_KEY	/BOBF/CONF_KEY (RAW16)
PARENT_KEY	/BOBF/CONF_KEY (RAW16)
ROOT_KEY	/BOBF/CONF_KEY (RAW16)
...	

If the legacy database table has already compliant fields to the BOPF default persistency layout (very rare case) or those fields can be introduced, the integration is possibly by just maintaining the corresponding table in the node configuration.

Data Integration on Application Layer Issues

Case 1: BOPF Default Persistency Layout is used

Issue

The legacy database table is usually used by another application. This application uses an own enqueue concept which needs to be obeyed. Before the BOPF modifies the entries of that legacy database table, a corresponding enqueue must be acquired (and later on released).

Solution

Reimplement the BOPF Lock and Unlock Action for the node that integrates the legacy table. Set both the locks for the legacy application and the ones for the BOPF. As soon as BOPF requires locks, your lock/unlock action will be invoked to acquire or release the lock.

Data Integration on Application Layer Issues

Case 2: Incompatible Database Layout

Issue

The primary key of the legacy database table is type-compliant to BOPF default persistency layout. However the name does not match the BOPF default persistency layout (e.g. the key not named „DB_KEY“). It is not possible to change the field's name.

Solution 1: Persistency Mapping (not recommended)

Use the persistency mapping tab of the BOPF Configuration UI to bind the different named field to the DB_KEY field. This is not possible in BOBX and Eclipse and should not be done at all.

Solution 2: Own DAC (not recommended)

Implement your own DAC by copying /BOBF/CL_DAC_TABLE and replace the SQL statements/coding accordingly. As this duplicates a lot of code which needs to be separately maintained, this should not be done.

Solution 3: Usage of Legacy DAC

The Legacy DAC allows to integrate legacy database tables having arbitrary fields as a common BOPF node.

Legacy DAC

How to use

1. Create a persistent node and maintain the BOPF Legacy DAC class as data access class
2. Maintain a unique alternative key named „DB_KEY“ on that node consisting of all the components of the legacy database table building the legacy key (can be more than one component)
3. If the node is not the ROOT node, maintain also a unique alternative key „PARENT_KEY“ (consisting of all legacy components building the parent key information) and the corresponding „ROOT_KEY“. If there is no ROOT_KEY alternative key, the legacy DAC will automatically concatenate the parent key information to simulate a ROOT navigation.
4. In case of self implemented queries, the mapping functionality of the legacy DAC can be used via its methods `map_to_bopf_key` and `map_to_legacy_key`.

Legacy DAC Restrictions

- Please be aware that in this case an own lock and unlock action class must be provided as the BOPF library lock class expects globally unique keys – those transient keys are only unique within their session but not cross session (see chapter „Action“ for action implementations). But as there is usually non-BOPF business logic operating on the legacy database table, the lock/unlock behavior always needs to be adapted.
- Please be aware that the transient keys must not be stored by the consumer as they will change for each session. Thus the consumer always has to start the transaction using an alternative key (or query) to get the current transient keys but is not allowed persist the transient keys.

Legacy DAC Principle

Consumer

KEY	ID	ID_TYPE	CREATED_BY
0	23	INV	SMITH
1	24	CDV	CARTER

KEY field is hidden by field properties (disabled)

BOPF

KEY	ID	ID_TYPE	CREATED_BY
0	23	INV	SMITH
1	24	CDV	CARTER

Legacy DAC +Mapping Table

KEY	ID	ID_TYPE	KEY	ID	ID_TYPE	CREATED_BY
0	23	INV	0	23	INV	SMITH
1	24	CDV	1	24	CDV	CARTER

Legacy Database Table

ID	ID_TYPE	CREATED_BY
23	INV	SMITH
24	CDV	CARTER

Field "ID" and "ID_TYPE" are the primary key components of the legacy table uniquely identifying each table entry
